

Multilayer ceramic capacitors

TPC, a subsidiary of THOMSON CSF, is a worldwide electronic component manufacturer, with over 40 years experience in ceramic capacitors and offers a complete package covering design, manufacture, just-in-time delivery and quality assurance for ceramic capacitors.

Our continued development in new materials and improved technology enables us to extend the range of products described in this brochure.

Our Sales, Marketing and Product Development Departments will provide you with full technical support to meet your requirements and help you for customized product design.

Introduction

GENERAL CHARACTERISTICS

The real characteristics of a capacitor can be described using conventional physical parameters and an equivalent electrical circuit displayed hereafter :

C the capacitance measures the capacitor aptitude to store electrical charges Q under a voltage V : $Q = C.V$

C_R the rated capacitance is obtained according to the building of the capacitor.

K the dielectric constant, specific to each material (less than 100 for type I materials, from 2000 up to 10 000 for type II materials),

S the surface of the electrodes,

t the thickness of the dielectric layer ; these parameters determine the value of the capacitor

$$C = K \frac{S}{t}$$

T.C. the temperature coefficient of the capacitance is expressed in ppm/°C for stable type I dielectrics.

°C/C is used for type II dielectrics and is expressed in % of change of the capacitance in a fixed temperature range.

U_R the rated voltage is the maximum voltage that can be applied to the capacitor in continuous operation.

It can be constituted by :

U_{DC} a direct current component

U_{AC} an alternative component with

U_P the peak voltage.

U_E the test voltage guarantees that the capacitor withstands U_R with a sufficient safety margin.

R_p represents the global losses (Polarization losses + insulation losses).
Under DC voltage the parallel resistance is reduced to :

R_i the insulation resistance, and measures the imperfection of the dielectric.

R_S or ESR (Equivalent Series Resistance) accounts for the imperfection of the conductivity of the electrodes and connections.

L_S or series inductance depends on the geometry of electrodes and connections, leads length ...

C_p takes into account dielectric environment of the capacitor (coating ...) but is generally neglected except to describe very high frequency behaviour of the capacitor.

R_p, R_s, L_s, C_p can be considered as parasitic effects. They generate energy losses and a dephasing

φ between voltage and current slightly different of 90°. The loss angle $\delta = (90^\circ - \varphi)$ is commonly used with

tg δ the tangent of loss angle which is also called :
DF or dissipation factor.

Q the quality factor is the ratio between the stored energy and the dissipated energy. It measures the quality of the capacitor and can be expressed as $Q = 1/\text{tg } \delta$

F being the frequency of the AC signal and

ω the pulsation of this signal with $\omega = 2 \pi F$

Z the complex impedance of the capacitor is therefore given by the relation (neglecting C_p) :

$$Z = R_s + j L_s \omega + \frac{1}{\frac{1}{R_p} + j C \omega} = R + j X$$

(the tangent of the loss angle $\text{tg } \delta$ can also be expressed as $\text{tg } \delta = \frac{R}{X}$

so, neglecting L_S for $L_S \omega < \frac{1}{C \omega}$

$$\text{tg } \delta = R_s C \omega + \frac{1}{R_p C \omega} + \frac{1}{R_p^2 C \omega}$$

F_{RS} the series resonance frequency of the capacitor is the frequency where the capacitance reactance is exactly compensated by the inductive reactance due to L_s

$$L_s \omega = \frac{1}{C \omega} \text{ or } \omega = \frac{1}{\sqrt{L_s C}} \text{ or } F_{RS} = \frac{1}{2\pi \sqrt{L_s C}}$$

F_{RP} the parallel resonance frequency occurs when L_s is compensated by C_p :

$$F_{RP} = \frac{1}{2\pi \sqrt{L_s C_p}}$$

Between F_{RS} and F_{RP}, the capacitor reacts as an inductance, but still blocking DC.

Introduction

The equivalent electrical circuit can be simplified using approximations according to the frequency :

- At $F = F_{RS}$ the circuit is reduced to

$$Z = R_s$$

- For $F > F_{RS}$ but below F_{RS}

$$Z = R_s + 1/jC\omega$$

$$\text{tg } \delta = R_s C \omega$$

- For low frequencies $Z = \frac{1}{\frac{1}{R_p} + jC\omega}$

$$\text{tg } \delta = \frac{1}{R_p C \omega}$$

VERY HIGH FREQUENCIES BEHAVIOUR OF LEADED CAPACITORS

- Below the serie resonance frequency a radial MLC may be represented by this equivalent circuit :

- L_s is essentially due to the leads (shape, pitch and length)

$$L_s = L_1 (\text{chip}) + L_2 (\text{leads})$$

This parasitic inductance has a large impact on the serie resonance frequency :

$$F_r = \frac{1}{2\pi \sqrt{L_s C}} \quad \text{so } F_r \text{ is } \approx a \cdot \frac{1}{\sqrt{L_s}}$$

Parallel leads inductance calculation

$$L_s (\text{nH}) = 0.4 \ln \left[\frac{2.1P}{\phi} + 0.25 \frac{P}{1} \right]$$

RELIABILITY

Ceramic capacitors reliability is related to two main factors :

• **A voltage derating** : life time is proportional to the power "n" of the derating applied :

$$\tau = a \left(\frac{U_{\text{rated}}}{U_{\text{use}}} \right)^n$$

$$n \approx 2 \text{ for NP0}$$

$$n \approx 3.4 \text{ for X7R}$$

THUS THE HIGHER $\left(\frac{U_{\text{rated}}}{U_{\text{use}}} \right)$ the longer the life.

• **A temperature derating** : life time is inversely proportional to the temperature of operation :

$$\tau = a \left(\frac{1}{T_{\text{use}}} - \frac{1}{T_{\text{rated}}} \right)$$

THUS THE LOWER the temperature of use, the longer the life.

* High reliability

Multilayer capacitors, especially moulded types can be produced in high reliability versions, according to the current ESA/SCC specifications and levels. Our MC and MK types appear on the European Space Agency qualified part list.

** Range extension

For high capacitance values and larger sizes, see catalogue "Ceramic capacitors for professional applications".

Taping characteristics

For automatic insertion, the following types can be ordered taped either in AMMOPACK or on REEL. For taped devices, it is necessary to specify the height (H or H_0) which is the distance between the tape axis (sprocket holes axis) and the sitting plane on the printed circuit board.

— Straight leads :

H represents the distance between the sprocket holes axe and the bottom plane of component body (base of resin or base of stand off).

— Kinked, flat and snap-in leads :

H_0 : distance between the sprocket holes axe and the base of the knee (kinked) or the bottom of the flat part (flat leads) or the waist.

CHARACTERISTICS OF THE TAPE (in accordance to IEC 286-2)

Value	Tolerance	Dimension characteristics	
18	+ 1 / - 0.5	W	Leading tape width
6	± 0.3	W_0	Adhesive tape width
9	+ 0.75 / - 0.5	W_1	Sprocket hole position
3 max		W_2	Distance between the tops of the tape and the adhesive
4	± 0.2	D_0	Diameter of sprocket hole
16/19.5	± 0.5	H_0	Distance between the tape axis and the seating plan of the component
30.5 max		H_1	Distance between the tape axis and the top of component body

Value	Tolerance	Dimension characteristics		
12.7	± 0.2	P_0	Sprocket holes pitch	
254	± 1	-	Distance between 21 consecutive holes 20 pitches	
0.7	± 0.2	1	Total thickness of tape	
2.54	5.08	+ 0.6 / - 0.1	F Lead spacing	
5.08	3.85	± 0.7	P_1 Distance between the sprocket hole axis and the lead axis	
12.7	± 1.0	P	Spacing of components	
0.5	0.6	0.63	± 10 %	d Lead diameter
0	± 1.3	$\text{°}P$	Verticality of components	
0	± 2	$\text{°}h$	Alignment of components	

REEL AND AMMOPACK PACKAGING

- A maximum of 3 consecutive components may be missing from the tape, surrounded by at least 6 filled positions. The number of missing components may not exceed 0.5 % of the total per packing module.
- The tape leader and trailer exhibit 8 or 9 blank positions.

Taping characteristics

Table below indicates the suffixes to be specified when ordering to get the required kink and packaging (12th and 13th digits of the product codification).

IDENTIFICATION - TRACEABILITY

On every packaging, you will find a bar code label.

This label gives systematic information on the type of product, part number, lot number, manufacturing date and quantity.

An example is given below :

(H)Lot: **1A69721080 /006** **970610**
 (Q)Qty: **500**
 (2W)TPC-PN: **MJ08G00104K--**

Lot number
 Manufacturing date (YYMMDD)
 Quantity per packaging
 Part number

This information allows complete traceability of the entire manufacturing process, from raw materials to final inspection.

Recommendation for use

RADIAL LEAD TYPES EC04/EC05/EC08

During the solder immersion time it is advisable :

- To keep the leads free into the holes of the board.
- Not to apply any strength on the component (in line with the leads or across the body).
- To lift the body of the component, at least by 2 mm from the PCB (applicable for EC04 2.54 mm straight leads). The component should not be exposed to the solder heat for more than the "time versus temperature" given by the chart below.

Quality and reliability

QUALITY SYSTEM

A high level of performance, quality and service has been achieved in setting up a quality system based on the ISO 9000 standard.

The system includes :

- a quality manual ensuring the proper organization,
- an incoming inspection,
- a manufacturing process control and a final inspection,
- reliability tests according to IEC 68, CECC 30600 and CECC 30700 standards,
- continuous improvements programs.

APPROVALS

The quality of our products and organization has been recognized by the following approvals :

* EC Types :

ISO 9002

Certificate of approval n° 928373

EN 100 114-1

Certificate of approval of manufacturer n° 004-96

CECC 30601 AND CECC 30701

See detailed data sheets on page 18

Qualified Parts List LNZ-44-04

Types CE 72/73/74 and CN 72/73/74

Qualified Parts List GAM-T1

Types CE 77/78/79 and CN 77/78/79

* Moulded types :

ISO 9001

Certificate of approval n° 928367

EN 100 114-1

Certificate of approval of manufacturer n° 032-93 issue 3

CECC 30601 and CECC 30701
