description

The TPIC2603 is a monolithic low-side driver which provides serial interface and diagnostics to control six on-board power DMOS switches. Each channel has independent OFF-state open-load sense, ON-state shorted-load/short-to-battery protection, over-battery-voltage-lockout protection, and over-temperature sense with fault status reported through the serial interface. The device also provides inductive voltage transient protection for each drain output. The TPIC2603 drives inductive and resistive loads such as relays, valves, and lamps.

Serial data input (SDI) is transferred through the serial register when $\overline{CS}$ is low on low-to-high transitions of the serial clock (SCLK). Each string of data must consist of 8 or 16 bits of data. A logic high input data bit turns the respective output channel ON and a logic low data bit turns it OFF. $\overline{CS}$ must be transitioned high after all of the serial data has been clocked into the device. A low-to-high transition of $\overline{CS}$ transfers the last six bits of serial data to the output buffer, places the serial data out (SDO) terminal in a high-impedance state, and re-enables the fault register. Fault data for the device is sent out the SDO terminal. The first bit of the shift register is exclusively ORed with the fault registers. When a fault exists, the SDI data is inverted as it is transferred out of SDO. Fault data consists of fault flags for over-temperature (bit 6) and shorted/open-load (bits 0-5) for each of the six output channels. Fault register bits are set or cleared asynchronously, when $\overline{CS}$ is high to reflect the current state of the hardware. The fault must be present when $\overline{CS}$ is transitioned from high to low to be captured and reported in the serial fault data. New faults cannot be captured in the serial register when $\overline{CS}$ is low.

6-CHANNEL SERIAL INTERFACE LOW-SIDE DRIVER

SLIS056A – FEBRUARY 1995 – REVISED MARCH 1996

description (continued)

When an over-current or shorted-load fault occurs, the channel transits into a low duty cycle pulse-width-modulated (PWM) signal as long as the fault is present. More detail on fault detection operation is presented in the device operation section of this data sheet.

The TPIC2603 provides pulldown resistors on all active-high inputs except SCLK. A pullup resistor is used on $\overline{\text{CS}}$.

The TPIC2603 is characterized for operation over the operating case temperature of -40°C to 125°C .

PRINCIPLES OF OPERATION

Figure 1. Switching Characteristics

serial interface

Control information is transferred into the TPIC2603 through the serial interface. The serial interface consists of a serial clock (SCLK), chip select ($\overline{CS}$), serial data input (SDI), and serial data output (SDO). Serial data is shifted, most significant bit (MSB) first, into the SDI shift register on the rising edge of the first SCLK after $\overline{CS}$ has transitioned from high to low. The controller must shift either eight bits or sixteen bits of data into the device with the last six bits of input data containing control information for the output drivers. Data bits preceding the output control information should be set to 0. A low-to-high transition on $\overline{CS}$ latches the contents of the last six bits of the serial shift register into the output buffer. A low input to SDI turns the corresponding parallel output OFF and a high input will turn the output ON (see Figure 2).

Figure 2. Serial Input Control

PRINCIPLES OF OPERATION

serial interface (continued)

Fault isolation data for each channel and global over-temperature status is transferred to the control device using the serial interface. Fault status for the TPIC2603 is captured as $\overline{CS}$ transits low. The fault interface monitors the SDI terminal and exclusively ORs the respective input control bit with the corresponding fault information bit stored in the fault register. Each exclusive ORed fault bit is transferred out the SDO terminal on the rising edge of the SCLK. Serial data can be transferred in 8-bit or 16-bit words as illustrated in Figure 4, with fault data appearing in the first 8-bits of serial output data. The $\overline{CS}$ must be transited high after the serial transfer has completely latched the new control data into the output control buffer and re-enable fault reporting on the device (see Figures 3 and 4).

NOTE A: MSB is the first bit transferred.

PRINCIPLES OF OPERATION

fault sense/protection circuitry

over-current/short-to-battery sensing and protection

The internal fault protection circuitry of the TPIC2603 monitors the drain current for each channel. Each channel offers two levels of protection from over-current conditions. The first level is a current-limit protection which through the internal FET prevents the switching current from exceeding the on-state current limit. The second level of protection transits the output to a low duty cycle PWM mode when the current exceeds the over-current sense threshold. The PWM mode protection is enabled approximately 70 μ s after the output has been turned on. The output remains in the PWM mode until the shorted-load condition has been corrected and then automatically returns to normal operation. Figure 5 illustrates device operation under an over-current or shorted-load condition.

SHORTED-LOAD

Figure 5. Shorted-Load Condition

TPIC2603

6-CHANNEL SERIAL INTERFACE LOW-SIDE DRIVER

SLIS056A – FEBRUARY 1995 – REVISED MARCH 1996

PRINCIPLES OF OPERATION

open-load/short-to-ground sensing

The TPIC2603 checks for open-load and short-to-ground conditions when the output is turned OFF. When the output turns OFF, a 40- μ A current source switches onto the drain. Under normal conditions, the load provides adequate current to overcome the current source and the drain voltage remains above the open-load detection threshold. When the output is open, then the current source pulls the drain low and an open-load condition is flagged. The open-load test is enabled approximately 70 μ s after the output turns OFF to allow the drain to stabilize. Figure 6 illustrates device operation under open-load conditions.

Figure 6. Open-Load Condition

over-voltage sensing and protection

The TPIC2603 monitors the V_{bat} input terminal to protect the device and load from over-battery voltage conditions. The device disables all of the drain outputs when V_{bat} goes above 35 V. An over-battery voltage hysteresis is provided to prevent the outputs from transiting ON and OFF erratically near the over-voltage threshold. The device automatically returns to normal operation after the over-voltage condition has been corrected. Figure 7 illustrates device operation under an over-battery voltage condition.

Figure 7. Over-Battery Voltage Condition

PRINCIPLES OF OPERATION

over-temperature sensing

The TPIC2603 monitors the junction temperature of the die to detect over-temperature conditions which may damage the device. When the junction temperature goes above approximately 170°C, the fault logic sets the global over-temperature fault bit. An over-temperature fault is reported using the serial interface on bit 6 (for 8-bit configuration) or bit 14 (for 16-bit configuration). The global over-temperature fault output in the serial data is exclusively ORed with the second bit (bit 6 for 8-bit configuration or bit 14 for 16-bit configuration) of data input to the SDI terminal. Bit 6 or bit 14 of the input data should be set low. Over-temperature faults are for informational purposes only and do not affect the state of the drains. Figure 8 illustrates device operation under over-temperature conditions.

THERMAL INFORMATION

The single-pulse curve represents measured data. The curves for various pulse durations are based on the following equation:

$$Z_{\theta JA} = \left| \frac{t_w}{t_c} \right| R_{\theta JA} + \left| 1 - \frac{t_w}{t_c} \right| Z_{\theta}(t_w + t_c) + Z_{\theta}(t_w) - Z_{\theta}(t_c)$$

Where:

$Z_{\theta}(t_w)$ = the single-pulse thermal impedance for $t = t_w$ seconds

$Z_{\theta}(t_c)$ = the single-pulse thermal impedance for $t = t_c$ seconds

$Z_{\theta}(t_w + t_c)$ = the single-pulse thermal impedance for $t = t_w + t_c$ seconds

$$d = t_w/t_c$$
